

Atelia New Updates Report

The items below are the larger, more involved parts of the requested updates. Each one is explained the same simple way: what happens today, what the update would change, and why it isn't a quick change to make.

1 Automatically Detecting Fabric Type From the Photo

CURRENT BEHAVIOR

When someone uploads a garment photo, they still have to type in the fabric themselves. The app doesn't look at the photo to figure out what the fabric actually is, so if what's typed doesn't match the real fabric, the tech pack can end up showing the wrong information.

NEW BEHAVIOUR

The app would look at the uploaded photo and work out the fabric type, whether it's knitted or woven, and a suggested weight and composition on its own — without anyone needing to type it in.

ISSUE

This means teaching the app to reliably recognize fabric just by looking at a picture, which is a capability we don't have today. It's also important to be upfront that this has a real limit: a photo can't fully capture things like fabric weight, stretch, or exact material percentages, so it's almost impossible to detect the fully accurate, exact fabric type from an image alone — at best, this gives a confident best guess, not a guarantee. It would also need to be tested carefully across many different garments before we can trust it enough to show customers and factories, so getting it right takes real time beyond just building it.

2 AI Validation Before PDF Generation

CURRENT BEHAVIOR

Right now, when a tech pack is generated, nothing checks whether all the details actually make sense together — it goes ahead and uses whatever was entered, even if something doesn't quite match.

NEW BEHAVIOUR

Before the final tech pack is produced, the app would send it back to the AI to double-check that everything lines up — for example, that the fabric suits the garment, the care instructions suit the fabric, and the measurements suit the chosen fit — and flag anything that looks wrong.

ISSUE

This means generating the tech pack and then sending it to the AI a second time just to re-check it, which adds an extra round of AI processing — and cost — to every single tech pack we create, on an ongoing basis, not just as a one-time build cost. It's also worth noting that our results are already quite accurate as they stand today, so this step would mostly be catching rare edge cases at a recurring cost, rather than fixing a common, visible problem.

3 Exact Logo Placement (e.g. "90mm below the shoulder seam")

CURRENT BEHAVIOR

Today, someone just picks a general area for the logo, like "left chest," and the app places it there as best it can — but it can't guarantee it lands in an exact spot.

NEW BEHAVIOUR

The logo would instead be shown at an exact distance, in millimeters, from specific reference points like the shoulder seam or the center of the garment, clearly marked on the drawing.

ISSUE

To do this properly, the garment needs to be drawn accurately with real measurements marked on it, which is not how our drawings are produced today. This is a foundational change to how the drawing itself is made, not a small addition on top.

4 A Real Technical (CAD) Drawing Instead of an AI-Generated Picture

CURRENT BEHAVIOR

The technical drawing in today's tech pack is generated by AI as a picture based on a written description. It looks like a proper technical flat, but it isn't built from real, exact measurements underneath.

NEW BEHAVIOUR

The drawing would instead be built from real data, so it's accurate and can carry exact measurements directly on it — matching how tech packs are done professionally in the fashion industry.

ISSUE

This is the biggest change on this list. It means building a completely new way of producing this drawing rather than improving the current one, and everything else that depends on exact placement — including the logo item above — relies on this being in place first.

5 Full Size-Graded Measurement Table

CURRENT BEHAVIOR

Right now, the app only offers a handful of generic measurements with the same standard tolerance applied to every garment, which isn't very specific or accurate.

NEW BEHAVIOUR

Based on simple choices like fit, gender, and a reference size, the app would generate a complete, accurate measurement table with correct tolerances across every size — the way factories expect to receive it.

ISSUE

Beyond building the feature itself, this needs a large, accurate set of real garment measurement data across every size and category we support. Gathering and validating that reference data will take considerably longer than building the feature.

6 Matching the Full Ralph Lauren-Style Tech Pack Format

CURRENT BEHAVIOR

Our tech pack today is a short, simple document made up of a couple of generated images plus some basic text — it's built to communicate a design idea quickly.

NEW BEHAVIOUR

The reference example shared is a full multi-page production document: a cover page, a full materials list with suppliers for every component, several detailed construction pages, and even sample approval records — a proper industry-standard manufacturing document.

ISSUE

This isn't something we can add gradually. Matching that format means rebuilding our entire tech pack output into a much larger, structured production document with several sections we don't have at all today. It's a significant shift in what our tech pack even is, and would need to be planned as its own dedicated project rather than an update to the current one.

Why these sit together

Items 3, 4 and 6 all point to the same underlying gap: today's tech pack is generated as a quick AI picture and a simple document, not built from real, structured data the way factory-grade tech packs need to be. Items 1, 2 and 5 are smaller in comparison, but still involve new capability the app doesn't have today. Taken together, these represent a genuinely different, larger version of the product — not a set of quick updates to the current one.

✓ Smaller Updates Already Within Scope

Separate from the larger items above, the following requested changes are straightforward and already planned for the next update:

- **Simpler fabric question** — replacing the current free-text fabric field with easy plain-language choices (e.g. "Soft T-shirt fabric," "Hoodie fabric," "Ribbed," "I don't know").
- **Embroidery thread color** — letting the customer specify a thread color, either matched to the artwork or picked from a standard code system.
- **Automatic care label generation** — generating the correct wash and care instructions automatically based on the fabric.
