

Atelia Feasibility Review V2

Updated scope following client feedback on the initial feasibility review

This is the V2 of the review.

1. Automatic Fabric Type Detection

Client Feedback

This is not considered a priority at this stage. The current approach is being kept: users remain free to choose whatever fabric or material they wish, and if the factory believes a different fabric would suit the project better, they can raise it directly with the user and provide their own recommendation.

Keep as current. No engineering work required.

2. Accurate Logo Placement

Client Feedback

This remains a high-priority item. The logo's shape, dimensions, and exact placement need to be clearly defined. To simplify delivery, the proposed approach keeps the logo's visual placement on the drawing exactly as it appears today, and adds the exact dimensions and placement as written text elsewhere in the tech pack, rather than requiring the numbers to be annotated directly onto the drawing itself.

Scope

This narrows the original scope. The drawing itself stays exactly as it is generated today, and what's added is a written text section in the tech pack showing the logo's shape, size, and placement details alongside the existing visual. Because the drawing itself remains general rather than precisely plotted, the written details and the image will not visually match one another — a reasonable trade-off for the reduced scope, but one that should be communicated clearly.

Complexity:

5.0 / 10.0

3. Embroidery Thread Colors

Client Feedback

The reliability concerns raised around automatic color detection are valid, and the AI should not attempt to extract or match thread color from artwork at all, since this limits creative freedom and does not produce a dependable result. The revised request is a single "Pantone Reference" field, allowing the user to directly specify the exact embroidery color they want.

Scope

This is a considerably smaller item than originally scoped. It no longer involves a color-standard selector or any AI reading of artwork — the user enters the Pantone reference themselves, and it is stored and displayed in the thread color section of the generated tech pack.

Complexity:

2.0 / 10.0

4. Automatic Care Label Generation

Client Feedback

The factory is the party best positioned to provide care instructions, since it is responsible for sourcing and supplying the fabric. Care label recommendations will be the factory's responsibility rather than something the app generates automatically.

Keep as current. No engineering work required.

5. Improved Measurement Generation (POM Table)

Client Feedback

This is a relevant feature for the long-term evolution of the project, but not a priority at this stage — effort should focus on improvements that are more essential and quicker to deliver right now.

Keep as current for this stage. No engineering work required at this time.

6. AI Validation Before PDF Generation

Client Feedback

The concern raised around repeated regeneration cycles and the cost they would add is valid, and the app should not generate multiple versions of the same tech pack to perform repeated validation. Instead, the goal should be to minimize inconsistencies from the outset, through more structured prompts and by guiding users more effectively through the input process. Reaching zero inconsistencies is an ideal rather than a realistic operational target.

Scope

This replaces the original validation-and-regenerate step with tightening the existing prompts and guiding the user more effectively through input, rather than adding a new AI check after generation. This does not involve any repeated generation or added cost, and the client has already accepted that this reduces inconsistencies without guaranteeing they are fully eliminated.

Complexity:

5.0 / 10.0

7. Measurement Chart and 2D CAD Flat

Client Feedback

The 3D render should not be removed — it is essential to the user experience and valuable for helping factories understand the design intent, and a full 2D CAD replacement is not the direction to take. That said, the underlying problem still needs to be fixed: the two visuals in the tech pack sometimes show different measurements, which leaves the manufacturer unsure which set of numbers is the correct reference. Full consistency between all measurements shown in the document is essential.

Scope

The 3D render stays exactly as it is today, and this does not move toward a 2D CAD replacement. What is required is ensuring every measurement shown throughout the document — across the 3D render, the technical flat, and the measurement chart — is drawn from the same underlying values, so nothing in the document ever contradicts itself. This does not guarantee pixel-perfect placement on the rendered image itself, since the render is still produced through the existing AI image-generation process, but it does guarantee the numbers shown throughout the document are always consistent.

Complexity:

7.0 / 10.0
